HEAD-MOUNTED DISPLAY SYSTEM

Background of the Invention

Existing displays have relatively low resolution, by their resolution and by their size and weight. imaging. Head mounted displays are generally limited aircraft pilots and for simulation such as virtual for a number of different applications including use by Head mounted display systems have been developed

of the wearer, where it will place a large torque on of gravity of the display from extending upward and importance, is the desirability of keeping the center relatively large distance from the eye. Of particular systems, these displays are often positioned at the and because of the size and weight of available

qnrind nse. the wearer's neck and may bump into other instruments torward from the center of gravity of the head and neck

The display needs to be as non-intrusive as resolution format similar to that of a computer the wearer of a helmet mounted display in high-There is a continuing need to present images to

or to the side of the user's head and employ reflective of liquid crystal devices that could be mounted above head mounted display devices have contemplated the use which incorporate earphones into the helmet. the user's eyes. Often these displays utilize helmets an image onto a surface or visor mounted in front of above or to the side of the user's head which project used analog cathode ray tube ("CRT") devices mounted compact system. Existing head mounted displays have possible, leading to the need for lightweight and

the user. optics to direct an image within the field of view of

Summary of the Invention

described hereinafter.

reference. of these patents being incorporated herein by 5,300,788 (issued April 5, 1994), the entire contents 27, 1993), 5,228,325 (issued November 2, 1993), and described in U.S. Patent Nos. 5,206,749 (issued April manufacture of head or body mounted displays is matrix electronic displays is highly suited for the material to produce small, high resolution active film techniques and/or thin film single crystal silicon The use of transferred thin expected to increase. for head mounted and body mounted applications is resolution matrix displays, the use of these systems to the development of small, light weight, high commercial, industrial and entertainment purposes. Due on the human body for numerous applications including and methods for mounting display and electronic systems The present invention relates generally to systems

A display holder 130 is positioned on the mounting frame 110 such that the mounting frame rails 111a, 111b are disposed within respective display holder channels area 134 and an aperture 132 through which light from the backlight 124 passes. The display holder 130 also has a geared rack 135 for use in adjusting the

backlight where there is a backlight for each primary display color (e.g., red, green, blue) and the switching of the light valve. In another preferred embodiment backlight is provided by direct ambient light 99. Through a light transmissive front housing section 10 and mounting frame 110.

The backlighting assembly 120 contains a backlight 124, which is preferably a cold cathode backlight. The backlight 124 is disposed in a white reflector 122, which reflects light from the backlight 124 onto the display panel. In a transmissive color display, the backlighting can be provided by a multicolor sequential packlighting can be provided by a multicolor sequential packlighting can be provided by a multicolor sequential

Mounted to the mounting frame is a backlighting assembly 120 for use in transmissive display systems.

The backlighting assembly 120 contains a backlight 124

FIG. 4 is an exploded view of the optical assembly for the head mounted display 1. A mounting frame 110 is adapted to be mounted to the inner surface of the mounting frame 110 has first and second guide rails and frame 110 has first and second guide rails displacement of the light value display panels. The displacement of the inter-pupil displacement will be discussed in more detail below.

resolution. The single crystal silicon film is particularly well suited for small, high resolution, high speed displays used in head-mounted computer system applications. An optional nitride layer 2020 can be formed over the pixel element 2011, as shown in FIG. 63B. An optional adhesion promoter (not shown) reson next be coated and baked onto the nitride layer can next be coated and baked onto the nitride layer promoter is not used.

A layer of polyimide, such as PiC Green O2 is spun

on over the circuit at a speed of 1,000 rpm for 90 seconds. The resulting structure is shown in FIG. 63C. The polyimide layer 2030 is about 1 to 5 microns thick. In a preferred embodiment, the polyimide layer 2030 is about 2 microns thick. The structure is then subjected to a solvent removal bake at 120°C for 60 seconds on a not critical. The structure is then subjected to a second or "beta" bake at 168°C on a hotplate for 90 seconds in vacuum contact. It is critical that the second or "beta" bake at 168°C on a hotplate for 90 seconds in vacuum contact. It is critical that the temperature be uniform in the beta bake step because the beta bake defines the develop processing the beta bake defines the develop processing

As shown in FIG. 63D, a photoresist pattern 2040 is applied to the structure. The positive photoresist dosage. The pattern is then developed with a standard fluid developer for 40 seconds. The developer is preferably a metal ion free developer such as Shipely preferably a metal ion free developer such as Shipely photoresist. The polyimide 2030 will develop with the photoresist. The structure is then rinsed in water and dried with nitrogen or clean compressed air.

The photoresist is then removed with a structure and structure is then removed with a structure and structure is then removed with a structure and structure and structure and structure and structure are structured with a structure and structure are structured with a structure and structure are structured as structure and structure are structured as structure and structure are structured as structured

characteristics.

OT

commetcially available carbon-based solvent which is

spun onto the structure. The resulting color filter structure 2035 shown in FIG. 63E is then hand baked between 200° C and 260° C for one hour in an oven. In a preferred embodiment, the baked temperature is 230° C. The above process is repeated for the red and the

There are many alternative color combinations for There are many alternative color combinations for

There are many alternative color compliations for formulations are: color coordinates, spectral formulations are: color coordinates, spectral

formulations are: color coordinates, spectral transmission, heat stability, color saturation and light stability. Depending on the application, an appropriate formulation can be chosen to maximize the thickness of the applied polyimide film can also be thickness of the applied polyimide film can also be thickness of the applied polyimide film can also be varied. In this case the tradeoff is between color varied. In this case the tradeoff is between color varied. In this case the tradeoff is between color saturation and spectral transmission. In the present saturation and spectral transmission is all three colors. If increased transmission is

critical, a slightly thinner coating can be used, but this can result in the sacrificing the desired level of color saturation.

After the color filter layer (RGB) has been

Tabricated, it is necessary to encapsulate the colored polyimides with some type of barrier or capping layer 2060. This step shown in FIG. 63F is important for a number of reasons. Dye can leach out of the polyimide causing changes in the actual color of the pixels, adhesive, liquid crystal if the color filter elements are disposed on the liquid crystal side of the active are disposed on the liquid crystal side of the active matrix or another medium. In addition colored

matrix, or another medium. In addition, colored polyimide, especially certain commercially available

PCT/US94/11659 EL#11/56 OM

-29-

judicated above can also be used to achieve the same leaching of the dye eliminated but also the heat and mounting to glass with adhesive, not only is the discovered that by encapsulating the polyimides with a relatively hot operating environments, but we have of applications using higher light intensity levels or degradation. This is an important problem in the case types are particularly sensitive to heat and light

light degradation problem. Other types of barriers as thin film coating such as silicon nitride, followed by

effects.

Horizontal and vertical synchronization signals are provided at TTL levels on respective incoming data lines 2313, 2314 from a VGA adapter or similar video source. A control processor 2412 examines the incoming outeo. A control processor 2412 examines the incoming source. A control processor 2412 examines the incoming source. A control processor 2412 examines the incoming of video stream and tracks mode changes, which provide for video stream and tracks mode changes.

.9142 signal on line 2417, and a select data signal on line a frame switch signal on line 2415, a select clock signal on line 2411, a pixel clock signal on line 2413, The dot clock regenerator 2414 provides a pixel data added or repaired, all with little manufacturing cost. Upgrading the EPROM allows functionality to be changed, (FPGAs), which are also programmed from the same EPROM. contained within Field Programmable Gate Arrays functionality of the program. Most digital logic is Read-Only Memory (EPROM) which simplifies upgrading the processor is contained within a Erasable Programmable The program for the setup and adjustment parameters. Programmable Read-Only Memory (EEPROM) is used to store Preferably, a non-volatile Editable Erasable mouse signal line 2309 to the computer, as required. hardware or provides remote mouse functionality over a over a remote signal line 2331 and either controls interprets input signals from a remote control device Optionally, the control processor 2412 signals the mode change to a dot clock regenerator detecting a mode change, the control processor 2412 variable frequency multi-scanning capability.

The dot clock regenerator 2414 recreates the pixels dot clock used by a computer to output pixels. The regeneration must be accurately controlled because it is very important to provide a clock that is centered over each pixel and does not drift. Thus, a clock must be recreated that can be used to sample a pixel and nove to the next pixel. The dot clock regenerator 2414 includes a phase locked loop (PLL) network and Voltage incontrolled Oscillator (VCO), which are responsive to the mode change signal over data line 2416. There is no standard for the frequency of the incoming video no standard for the frequency of the incoming video

·pəsn

2473, 2483 from a temperature measurer 2470 or light meter 2480. The video amplifier 2452, bias network 2454, and a video switch 2456.

The analog video signal from line 2441 is provided

to the video amplifier 2452. The video input 2441 is amplified by an amount determined by the contrast (gain) control voltage 2351 generated by a digital-to-analog (D/A) converter 2350. Because the done by a back porch clamp (not shown). The Brightness clamp which is obtained from the D/A converter 2350.

The feedback for the clamp is taken from the main video outputs, which closes the loop around the full video path. In a preferred embodiment, this block is implemented by a National Semiconductor LM1201 implemented by a National Semiconductor is saphifier, although other suitable amplifiers can be amplifier, although other suitable amplifiers can be

complementary outputs from the video amplifier 2452. A normal output is positive-white from a (clamped) level a few volts above ground. An inverted output is negative white from a few volts below the positive in phase, and have the same gain because they are preferably taken from the same output transistor. Alternatively, the amplifier gain can be nonlinear and have the same output transistor.

(e.g., gamma functions). The normal and inverted applitier signals are fed to a bias network 2454.

The bias network 2454 is an RC network that biases the two outputs of the video amplified 2452 toward each other. Those outputs can never reach the same voltage, due to the nature of the output stage. But the inputs to the drive amplifiers 2458 should be capable of

- 49-

from the bias network 2454 are fed to the video contrast and brightness adjustment. The output signals crossing over in some cases, to allow a full range of
